Frontiers in Ecology and the Environment - Subscription (non-OA) Journal. Frontiers in Ecology and the Environment is a Subscription-based (non-OA) Journal. Publishers own the rights to the articles in their journals. Anyone who wants to read the articles should pay by individual or institution to access the articles.

The subject matter is compiled in 22 chapters covering broadly the major issues of fungal ecology, diversity and metabolites. Serves as a valuable source of information on

frontier areas of mycology: ecological amplitudes, conservation, novel methods of assessment and bio-prospecting.

Six OTUs were classified within Glomeromycota, known as obligate root symbionts with no previous records from leaves. Five members of Basidiomycota, which are rare in aquatic environments, were identified in the stream-immersed litter only. Overall, our study demonstrates that foliar microfungi contribute to fungal diversity in submerged litter.

The researchers observed real-time evolutionary change in the fungal parasite. The finding that a fungal parasite can quickly adapt to a population of genetically identical cyanobacteria, but not to populations with different genetic variants, helps explain why a high degree of diversity in populations may be valuable for their preservation.

Frontiers in Fungal Ecology, Diversity and Metabolites

Here, using soil fungal data collected from 28 forest reserves across China, we explored the latitudinal diversity gradients of overall fungi and different fungal functional guilds, including putative plant pathogens, EMF, and saprotrophic fungi.

Loop | Peter H W Biedermann

These interactions occur in the presence of additional microbes that can modify fungal phenotypes, such as endohyphal bacteria (EHB). Here we examine the occurrence, diversity, and taxonomic composition of EHB

in fungi that colonize seeds and leaves of plants in tropical forests.

The kingdom Fungi is a megadiverse group represented in all ecosystem types. The global diversity and distribution of fungal taxa are poorly known, in part due to the limitations related to traditional fruit-body survey methods. These previous hurdles are now being overcome by rapidly developing DNA-based surveys.

Fungal α -diversity is known to be greater in arable soils than in grasslands or forests (Szoboszlay et al., 2017). Potential mechanisms for this include: (i) increased nutrient availability due to fertiliser input (Szoboszlay et al., 2017), and (ii) beneficial disturbance
